(54) Fiber optic terminal interface.

(57) The present invention is a communications link between a data processing apparatus and a user input/output terminal. In the data processing apparatus (120) a data transmitter multiplexes monochrome digital video data (211) with Manchester encoded ancillary data such as keyboard control data (212) and sound synthesis data (213) for transmission via a first communications link (122). The Manchester encoded data has a clock rate tied to the video dot rate of the digital video data and is transmitted during the horizontal retrace interval. The receiver (230) in the terminal (130) uses the self clocking nature of the Manchester encoded data for clock detection, demultiplexing and synchronization. This receiver (230) then generates video data (231), keyboard control data (232) and sound synthesis data (233) for utilization and a clock signal (235) for controlling return data. A data transmitter (240) in the terminal (130) receives keyboard input data (241), mouse input data (242) and speech input data (243) for encoding in conjunction with the clock signal (235) and transmission to the data processing apparatus (120) via a second communications link (126). A second receiver (220) is connected to the second communications link (126) and generates demodulated keyboard input data (221), mouse input data (222) and speech input data (223). In the preferred embodiment the two communications links (122, 126) comprise optic fibers.

## FIBER OPTIC TERMINAL INTERFACE

BACKGROUND OF THE INVENTION

The present invention relates to the manner of connecting a user input/output terminal to a data processing system. Such a connection is required in the case in which a single data processing system supports a number of user terminals, or in  
5 the case in which a data processing system supports only a single user terminal which is located remotely from the data processing system. A communications link between the data processing system and the user terminal is required in order to provide the required interaction between these elements. The  
10 present invention relates to this communications link.

The user terminals of the type to which the present invention is applicable include a variety of input and output devices. The major output device used in such user terminals is a video display. A video display is typically a raster  
15 scanned cathode ray tube which provides graphic and pictorial information to the user. The terminal may also include a tone generator for generating tones which may serve as audible alarms or the like. Such a user terminal may further include some type of synthetic speech synthesis device which provides a  
20 machine generated output in a human language which may be understood by a naive user. In addition, should there be a limit on types of ancillary data, such a device may include one or more indicator lights which are controlled by the data processing system.

25 User terminals of the type to which the present invention is applicable typically employ a manually actuated typewriter style keyboard as the major input device. This keyboard is employed by manually depressing one or more keys to compose textual messages for transmission to the data processing  
30 system. Another type of widely used input device is a mouse. A mouse is a pointing device employed with a video display screen. A cursor or indicating device on the screen is moved in correspondence to the movement of the mouse on a surface

such as a desk adjacent to the user terminal. A mouse of this type may also include one or more user actuatable switches which serve to transmit condition signals from the user to the data processing apparatus. In addition, it is possible for  
5 such a user terminal to include a microphone for receiving spoken messages which may be interpreted in conjunction with a speech recognition system.

It can be seen that even the simplest type of user terminal requires bidirectional communication. In the event  
10 that the data processing system transmits video data to the user terminal, this communication must be at a high bit rate. This is in contrast to data such as from a keyboard which is passing from the user terminal to the data processing system, which is ordinarily of a low bit rate. Thus, an interface of  
15 the type to which the present invention pertains includes bidirectional communication of varying bit rates.

There are mechanical and electrical requirements for the communications link of this type. Firstly, the weight and bulk of the communications link between these two systems needs to  
20 be minimized. A minimal weight and bulk will permit easier installation of this communications link. In addition, it is also desirable that the cable employed for this purpose be flexible in order to be able to better conform to the routing requirements of any specific installation. Typically, such  
25 communications links would be installed in office locations such as used by an engineer or other technical worker. Other electronic devices are commonly employed in such an environment.

This brings to mind the electrical requirements for such a  
30 communications link. Electromagnetic interference (EMI) and radio frequency interference (RFI) are types of radiated energy which might emanate from such a communications link. Particularly in the case in which a high bit rate is required, therefore requiring high frequency signals on the communica-  
35 tions link, it is necessary to make special provisions to

minimize the amount of energy radiated. Minimization of this radiated energy serves to minimize the interference of this particular communications link with other electrical systems employed in this same area.

5        On a similar line, it is desirable to provide a type of communications link which minimizes electrostatic discharge (ESD). The data processing system and the user terminal would typically be constructed using metal oxide semiconductor (MOS) devices. These MOS devices are highly susceptible to static  
10 electricity and are vulnerable to electrostatic discharge. Therefore, it would be highly desirable to provide such a communications link which minimized or eliminated electrostatic discharge.

A further problem with such communications links is ground  
15 shift. Electrically shielded high frequency copper wires typically use wire shields tied to chassis ground. When two chassis are located remotely, it is possible that they are tied to differing branches of the electric power lines and thus have differing chassis ground potentials. This causes unwanted  
20 current through the wire shield which can cause numerous problems.

BRIEF DESCRIPTION OF THE DRAWINGS

These and other advantages and features of the invention will be further described below in the detailed description of the invention taken in conjunction with the drawings in which:

5 Figure 1 illustrates the general outline of the data processing system and user terminal combination to which the present invention is applicable;

Figure 2 illustrates the details of the transmitters and receivers and the dual channel communications system according  
10 to the preferred embodiment of the present invention;

Figure 3 illustrates the form of the data transmitted from the data processing system to the user terminal in accordance with the preferred embodiment of the present invention;

Figure 4 illustrates the preferred embodiment of the  
15 transmitter located within the data processing system of the present invention;

Figure 5 illustrates the preferred embodiment of the receiver within the user terminal;

Figure 6 illustrates the preferred embodiment of the  
20 transmitter within the user terminal; and

Figure 7 illustrates the preferred embodiment of the receiver within the data processing system.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

The features and particulars of the preferred embodiment of the present invention will now be described in detail. Figure 1 illustrates the general construction of an apparatus such as employed in the preferred embodiment of the present invention. This apparatus includes a central processing unit 110, a graphics controller 120 and a user terminal 130. The central processing unit 110 is in bidirectional communication with graphics controller 120 via communication links 112 and 116. Similarly, graphics controller 120 is in bidirectional communication with user terminal 120 via communication links 122 and 126. A dashed line 140 encloses both central processing unit 110 and graphics controller 120. This dashed line 140 indicates the parts which are included within a single enclosure. In the event that computing system 100 serves a single user, it would be desirable to place all of these units within a single enclosure. This would provide the communication links 112 and 116 and the communication links 122 and 126 were within this single enclosure making the mechanical and electrical problems of providing these communication links much simpler. However, it is anticipated that the computing system of the preferred embodiment is so large in size that it is impractical to place all three of these elements within the same enclosure. If the size of the data processing apparatus is such that it cannot all be placed within one enclosure, then it is necessary to employ multiple enclosures and to interconnect the apparatus between these enclosures. As illustrated in Figure 1, there is a natural division of function among the central processing unit, the graphics controller and the user input/output terminal. Thus these units could be placed in three separate enclosures or they could be disposed in two enclosures in two differing manner. In the first of these the central processing unit and the graphics controller are in one enclosure and the user terminal is in the other as illustrated in Figure 1. In the other way

the central processing unit is in a single unit and the graphics controller and the user terminal share one enclosure. Because the data processing apparatus of the preferred embodiment of the present invention employs a high resolution  
5 video display, the communication between central processing unit 110 and graphics controller 120 is necessarily of a high data rate. Therefore it is considered advantageous to enclose both central processing unit 110 and graphics controller 120 in the same enclosure.

10 In accordance with the preferred embodiment, central processing unit 140 and graphics controller 120 are placed within the same enclosure 140. Therefore, communication links 122 and 126 must pass from enclosure 140 to user terminal 130. In this event, both communication links 122 and 126 encounter  
15 the mechanical and electrical problems noted above.

Figure 2 illustrates the configuration of the transmitters and receivers on communication links 122 and 126 in accordance with the preferred embodiment of the present invention. Transmitter 210 and receiver 220 are located within graphics  
20 controller 120. Receiver 230 and transmitter 240 are located within user terminal 130.

Transmitter 210 transmits data on communication link 122 to receiver 230. Transmitter 210 receives video input 211, keyboard input 212 (which may control keyboard indicators or  
25 control the keyboard configuration) and sound input 213. Receiver 230 receives this data on communication link 112. Receiver 230 then separates out video data 231, keyboard data 232 and sound data 233 for application to those portions within user terminal 130 which employ this data (not illustrated).  
30 These features are conventional in nature. Receiver 230 also outputs clock signal 235 which is derived from signals received on communication link 122.

In accordance with the preferred embodiment of the present invention, both communications links 122 and 126 are formed of  
35 optical fibers. The use of optical fibers for the

communications links minimizes the mechanical and electrical problems with such communications links. Firstly, fiber optic cables are very small and consequently such cables have a relatively small weight and bulk. These cables are also  
5 flexible in comparison to the prior art copper coaxial cables. Thus fiber optic cables contribute to the solution to the mechanical problems associated with such communications links.

In addition, fiber optic cables contribute to the solution to the electrical problems with such communications  
10 link. There are no oscillatory electrical currents in fiber optic cables. This lack of oscillatory electrical currents, which is in contrast to the prior art copper coaxial cables, is the factor which makes fiber optic cables advantageous. The major causes of electromagnetic interference (EMI) and radio  
15 frequency interference (RFI) are those oscillatory electrical currents. Thus fiber optic cables substantially reduce this source of electrical problems. In addition, fiber optic cables are nonconducting. For this reason there is also a substantially reduced chance of damaging electrostatic  
20 discharge (ESD) from fiber optic cables as opposed to the prior art copper coaxial cables. Note that such a fiber optic link prevents an electrostatic discharge path between the user terminal, where static is most likely to be generated, and the central processing unit, where it is most damaging.

25 Receiver 220 within graphics controller 120 receives data on communications link 126 from transmitter 240 located in user terminal 130. Transmitter 240 has applied to it keyboard data 241, mouse data 242 and speech data 243. Transmitter 240 also receives clock 235 from receiver 230. Transmitter 240 takes  
30 the incoming data together with the clock signal and generates a transmission on communications link 126 in the form required by communications link 126. This is then applied to receiver 220 within graphics controller 120. Receiver 220 converts the signal from communications link 126 into its component signals,  
35 namely keyboard data 221, mouse data 222 and speech data 223.

This data is then applied to central processing unit 110 for processing by that element.

Figures 3(A) to 3(C) illustrate the format of the preferred embodiment of the communications from graphics controller 120 to user terminal 130 on communications link 122. Figure 3(A) illustrates the form of data transmitted on communications link 122 during normal horizontal scan periods. In the preferred embodiment the video signals are transmitted in digital form. For a monochromatic display each pixel of the display can be represented by a single bit. This digital video data is transmitted in a set of horizontal scan lines in accordance with the prior techniques concerning analog video signals. Figure 3(B) illustrates the form of communications transmitted during vertical retrace intervals. Lastly, Figure 3(C) illustrates the form of the coded data 320 transmitted during the horizontal retrace intervals.

Signal 310 illustrates the parts of the data transmitted on communications link 122 during normal horizontal trace intervals. This signal 310 is composed of uncoded video data 315 and coded data 320. The uncoded data 315 is preferably a single bit for each pixel for each horizontal line on the video display. Thus, for example, a zero in a particular bit position would cause the corresponding pixel on that line within the video display to be black. On the other hand, a one in that bit position would cause the corresponding pixel on the video screen to be white. This is according to the preferred embodiment employing digital video signals. Communications link 122 could carry analog signals to enable a gray scale. The required bit rate for the communications link is for the most part set by the number of pixels on the video screen and therefore the number of bit positions within uncoded video data 315. For example, for a high quality video screen having 1,000 lines of 1,000 pixels each, each uncoded video data portion 315 must have 1,000 bits and it requires transmission of 1,000 uncoded video data portions 315 in order to transmit the entire

video screen. Therefore, each video screen includes approximately one million bits. In order to achieve a flicker free display in the presence of moving attributes, it is ordinarily considered necessary to transmit 60 complete frames per second. Thus, the data rate for such a high quality video screen is at least 60 million bits per second.

Coded data 320 of signal 310 contains the keyboard and sound portions together with other auxiliary data. This coded data 320 is further illustrated in Figure 3(C).

Signal 330 illustrates the signal on communications link 122 during the vertical retrace interval. As is well known in the art, during the vertical retrace interval of a raster scanned picture the cathode ray spot is returned to the upper right hand corner. During this time interval, which may equal the time interval of several horizontal scans, the incoming video data is ignored. Therefore, the video data transmitted during this portion of a scan cycle is unimportant. In the preferred embodiment, a square wave signal 335 is transmitted during this vertical retrace interval. In addition, coded data 320 is transmitted at the end of each of the horizontal scan lines which make up the vertical retrace interval, in the same manner as in the normal horizontal scan signal 310.

Coded data 320 is illustrated in detail in Figure 3(C). The coded data 320 includes sync pattern 321, vertical sync 322, keyboard data 323, speech data 324, sound data 325 and test data 326. Sync pattern 321 is employed to signal to the user terminal the end of a horizontal scan line. In an analog video system the horizontal sync signal is communicated via an analog signal outside the range of permissible video signals. In the video system of the preferred embodiment, the video data is transmitted as a digital signal. Therefore, it is necessary to provide another means for identifying the end of a horizontal scan line. The sync pattern 321 is a predetermined set of bits. As will be more fully explained below in

conjunction with Figure 5, the receiving apparatus in the user terminal detects this predetermined set of bits corresponding to sync pattern 321 as will be further explained below, this also initializes the decoding of coded data 320.

5        Vertical sync 322 serves a function similar to sync pattern 321. Vertical sync 322 is employed to indicate when a frame reset is required.

10        The remaining portions of coded data 320 corresponds to data transmitted from the graphics controller 120 to user terminal 130. Keyboard data 323 serves to control any keyboard indicators and to control the configuration of the keyboard. Speech data 324 is employed in conjunction with a speech synthesis circuit. Speech data 324 specifies the particular synthetic speech to be produced at user terminal 130.

15        Similarly, sound data 325 is employed in conjunction with an audible sound generator. Sound data 325 is employed within user terminal 130 to indicate the type of sounds to be produced by this sound generator. Lastly, test data 326 is employed by user terminal 130 in order to test various aspects of this unit

20        under the control of the central processing unit 110.

It would be understood by those skilled in the art that the foregoing description of coded data 320 is not exhaustive. It would be clear to those skilled in the art that other forms of coded data may be transmitted via coded data 320 than those

25        illustrated in Figure 3 and noted above. In particular, it should be noted that ordinarily the data rate required for the data within coded data portion 320 is much less than the data required for uncoded video data 315. Therefore, coded data 320 may be transmitted at a much lower bit rate. This much lower

30        bit rate would require much less sophisticated decoding than would be required if it were transmitted at the rate of the uncoded video data.

Figure 4 illustrates transmitter 400 located within the graphics controller. Transmitter 400 generates an optic output

35        on communications link 122 which is then applied to the

receiver in user terminal 130. Transmitter 400 includes parallel to serial shift register 410. Parallel to serial shift register 410 has numerous data and control inputs supplied thereto. The data inputs include vertical sync 411,  
5 keyboard data 412, sound data 413, speech data 414, sync code 415 and the test data 416. Although each of these data inputs is illustrated as including a single line, it should be understood that each of these signals may include a plurality of bits applied to parallel to serial shift register 410.  
10 Parallel to serial shift register 410 is controlled by load signal 417 and shift signal 418 from timing and control logic 420. The output from parallel to serial shift register 410 is serial data 431.

Timing and control logic 420 performs the major control  
15 functions within transmitter 400. Timing and control logic 420 receives a clock input 421 and a horizontal synchronization input 422. Timing and control logic 420 then produces various signals at the time required by the other elements of transmitter 400. Timing and control logic 420 produces load  
20 signal 417 and shift signal 418 to parallel to serial shift register 410. Load signal 417 is applied to shift register 410 when shift register 410 is being loaded with the various data bits. Shift signal 418 causes shift register 410 to no longer receive inputs but to shift its contents out as serial data  
25 431 to Manchester encoder 430.

Manchester encoder 430 receives the serial data 431 from shift register 410 and further receives clock 432 from timing and control logic 420. Clock 432 may have a different frequency than clock 421 applied to timing and control logic  
30 420. Manchester encoder 430 takes an exclusive OR of serial data 431 and clock signal 432 thereby producing encoded data 441. This encoded data 441 is applied to multiplexer 440.

Multiplexer 440 serves to combine various signals under the control of timing and control logic 420. Multiplexer 440  
35 receives the encoded data 441 from Manchester encoder 430.

Multiplexer 440 also receives uncoded video 442. Multiplexer 440 receives square wave 443 and control 444 from timing and control logic 420. Multiplexer 440 operates in accordance with control 444 to apply one of encoded data 441, video data 442 or square wave 443 to electrical output 445. During a normal horizontal scan period, video data 443 is coupled to electrical output 445. During a horizontal retrace interval, encoded data 441 is applied to electrical output 445. During the horizontal retrace interval of the set of scan lines corresponding to vertical retrace, square wave 443 is coupled by multiplexer 440 to electrical output 445 in place of video data 443. Thus, multiplexer 440 serves to assemble and combine the signals illustrated in Figure 3. Timing and control logic 440 places the proper signals on control 444 enabling multiplexer 440 to perform this function.

Fiber optic transmitter 450 converts an electrical signal into an optical signal. In accordance with the preferred embodiment of the present invention, the communications link 122 between graphic controller 120 and user terminal 130 is via an optic fiber. Fiber optic transmitter 450 receives electrical output 445 from multiplexer 440. Fiber optic transmitter 440 then converts this to optical output 451. This optical output 451 is applied to an optic fiber (not shown) which forms communications link 122.

Figure 5 illustrates receiver 500. Receiver 500 is located in user terminal 130 and receives an input on communication link 122. This appears as optical input 511 to fiber optic receiver 510. As explained in further detail below, receiver 500 generates outputs for use by the utilization portions of the user terminal.

Fiber optic receiver 510 serves as the input to receiver 500. Fiber optic receiver 510 receives an optical input 511 from communications link 112. Fiber optic receiver 510 then converts this optical input into an electrical input 512 which is applied to both video gate 515 and Manchester decoder 520.

As previously described in conjunction with Figure 3, optical input 511 includes portions corresponding to uncoded video data 315 on square wave signal 335 and portions corresponding to coded data 320. Video gate 515 and Manchester decoder 520 are employed to separate these respective components.

Electrical input 512 is applied to Manchester decoder 520. Manchester decoder 520 is constructed in order to recover the clock signal from Manchester encoded data. Once this clock signal has been recovered, then it is possible to separate this encoded data from the encoded video data. Manchester decoder 520 then produces clock signal 521 and data signal 522.

Clock signal 521 and data signal 522 are applied to sync pattern detector 525. Sync pattern detector 525 checks to determine whether the sync pattern 321 has been received. When sync pattern 321 has been received, a sync signal 526 is generated. The reception of sync pattern 321 is most important as it marks the end of the uncoded video data 315 or square wave signal 335 and the beginning of coded data 320. This is clearly an important time, and sync signal 526 signals the detected reception of sync pattern 321.

Major timing and control functions in receiver 500 are carried out by event counter 530. Event counter 530 works in conjunction with windowed gate 531, phase locked loop oscillator 532 and reset select gate 533 in order to provide proper timing and control signals for the output portions of receiver 500. Then event counter 530 counts pulses received from phase locked loop oscillator 532. Dependent upon this count, event counter then generates signals at its output such as gate signal 534, sync signal 535, valid signal 536, gate signal 537 and reset signal 538.

Phase lock loop oscillator 532 generates timing pulses used by event counter 530 to control the various events in receiver 500. Phase locked loop oscillator 532 is in turn controlled by windowed gate 531. Windowed gate 531 receives sync signal 536 from sync pattern detector 525 and a gate

signal 534 from event counter 530. Windowed gate 531 applies a rate signal to phase locked loop oscillator 532 in order to control its frequency and thereby the timing of event counter 530. This rate signal is dependent upon the rate at which sync signal 526 is received from sync pattern detector 525. Gate signal 534 is employed in order to prevent false rate signals caused by false detection of a signal pattern. Event counter 530 produces gate signal 534 in order to enable windowed gate 531 only during a predetermined interval near the expected time of arrival of sync pattern 321 and hence sync signal 526. Preferably, gate signal 534 is of a variable duration depending upon the quality of the phase lock on the sync pattern 321. That is, window gate 531 would be enabled for longer periods under the control of gate signal 534 when a good phase lock has not been achieved. On the other hand, windowed gate 534 would only be enabled for a short period of time once the quality of the phase lock has improved. Thus, the timing of events from event counter 530 is in phase with the reception of sync pattern 321 from communication link 122.

The count within event counter 530 is reset by reset select gate 533. Reset select gate 533 resets event counter 530 based upon two contingencies. In the normal case, reset signal 538 from event counter 530 occurs nearly simultaneously with sync signal 526. In this event, reset select gate 533 resets event counter upon reception of reset signal 538. This prevents any slight jitter in reception and detection of sync pattern 321 from interfering with normal operation. If reset signal 538 and sync signal 526 drift apart in time further than a preset limit, and if this condition lasts for several cycles, then reset select gate 533 switches to operation upon reception of sync signal 526. This continues until reset signal 538 and sync signal 526 are again received within the preset limit apart, whereupon normal operation resumes. This prevents false triggering to continue in the event that reset signal 538 drifts away from sync signal 526.

Once event counter 530 has been properly set and in synchronization with the reception of sync pattern 321, event counter 530 properly controls the output portion of receiver 500. Event counter 530 produces a gate signal 537 which is applied to video gate 515. This permits video gate 515 to pass the electrical input 512 to video output 513. This gate signal 537 is applied during the period of reception of uncoded video data 315. The time at which video gate 515 is opened is timed in conjunction with the internal count of event counter 530 in order to correspond to the interval of reception of uncoded video data 315. Thus, video output 513 includes successive scan lines of uncoded video data 315 with coded data 320 removed. During vertical retrace intervals, video gate 515 is turned off so that neither square wave signal 335 nor encoded data 320 appears at video output 513.

Data multiplexer 540 receives data signal 522 from Manchester decoder 520 and a valid data signal 536 from event counter 530. The data signal 522 from Manchester decoder 520 is a serial bit stream which is loaded into data de-multiplexer 540 during a loading phase. Upon reception of a valid data signal from event counter 530, data multiplexer 540 generates parallel outputs to various portions of user terminal 130. These outputs include keyboard output 541, sound output 542, speech output 543 and test output 544. These multibit data signals are utilized by various portions of user terminal 130 in a conventional manner. When valid data signal 536 is not received from event counter 530, then data demultiplexer 540 does not generate these various output signals.

Horizontal sync generator 550 and vertical sync generator 555 generate synchronization signals to the video portion of user terminal 130 in order to control the horizontal and vertical scanning motion. Both horizontal sync generator 550 and vertical sync generator 555 receive sync signal 535 from event counter 530. This sync signal 535 is received from event counter 530 other than directly from sync pattern detector 525

in order to reduce the instances of false sync detection. Event counter 530 with windowed gate 531 and phase locked loop oscillator 532 provides a more reliable indication of the reception of sync pattern 321 with fewer false indications than  
5 that received directly from sync pattern detector 525. Horizontal sync generator 550 generates horizontal sync signal 551 directly from sync signal 535. On the other hand, vertical sync generator 555 receives an additional input. This additional input is vertical sync signal 545. Note that  
10 vertical sync signal 322 is a part of coded data 320. In order to detect a valid vertical sync signal, causing a frame reset in the video display of user terminal 130, it is necessary to receive both sync pattern 321 and vertical sync 322. Vertical sync 322 is a portion of coded data 320 and thus data signal  
15 522 applied to data demultiplexer 540. From the occurrence of both sync signal 535 and vertical sync signal 545, vertical sync generator 535 generates vertical reset signal 536. This is employed in the video display terminal in order to reset the video frame.

20 Figure 6 illustrates transmitter 600 which is located in user terminal 130. Transmitter 600 transmits keyboard, mouse and speech data from user terminal 130 to graphics controller 120 via communications link 126.

Input data to transmitter 600 is applied to parallel to  
25 serial shift register 610. This includes keyboard data 611, mouse data 612 and speech data 613. As explained above in conjunction with Figure 4, each of these data inputs preferably includes a plurality of parallel bits. This data is loaded into parallel to serial shift register 610 in accordance with  
30 load command 614 from timing and control logic 620. Upon reception of shift signal 615, parallel to serial shift register 610 applies serial data 631 to manchester encoder 630.

Timing and control logic 620 performs the major timing and control functions of transmitter 600. Timing and control logic  
35 620 receives clock signal 621 from receiver 500. This clock

signal 621 is related to clock signal 521 produced by Manchester decoder 520. By this means, transmitter 600 is tied to the same Manchester clock signal as transmitter 400 in graphics controller 120.

5       Timing and control logic 620 produces load signal 614 and shift signal 615 in the proper time to enable parallel to serial conversion of the input data by parallel to serial shift register 610. Timing and control logic 620 also produces clock signal 632 to be applied to Manchester encoder 630. Manchester  
10 encoder 630 operates to combine OR data 631 and clock 632 to produce encoded data 641.

      Timing and control logic further generates control signal 642 which is applied to sync signal adder 640. Sync signal adder 640 receives encoded data 641 from manchester decoder 630  
15 and add a sync signal similar to sync pattern 321 of coded data 320 to the encoded data 641. The time at which this sync signal is applied is controlled by control signal 642. Sync signal adder 640 thus produces electrical output 645.

      Fiber optic transmitter 650 receives electrical output  
20 645. Fiber optic transmitter 650 produces optical output 651 corresponding to electrical output 645. This optical output 651 is applied to an optic fiber (not shown) forming communications link 126. Thus, the keyboard, mouse and speech data is applied to communications link 126.

25       Figure 7 illustrates receiver 700 located in graphics controller 120. Receiver 700 is connected to communications link 126 and receives the signals transmitted by transmitter 600.

      Receiver 700 includes fiber optic receiver 710 which  
30 receives optical input 711. This is from the optic fiber which forms communications link 126. In accordance with the received optical input 711, fiber optic receiver 710 generates electrical input 712.

      The electrical input 712 is applied to Manchester decoder  
35 720. In a manner similar to that described above in

conjunction with Manchester decoder 520, Manchester decoder 720 generates clock 721 corresponding to the clock 632 employed in Manchester encoder 630 and data 722. This data 722 corresponds to the original data received by transmitter 600.

- 5        Clock 721 and data 722 are applied to serial to parallel shift register 730. The parallel outputs from serial to parallel shift register 730 are applied to output latch 740. Output latch 740 also receives a latch clock signal 726 from sync detector 725. Sync detector 725 receives electrical input  
10 712 and generates the latch clock signals 726 upon detection of the appropriate sync signal. This sync signal is the sync signal applied to the encoded data by sync signal adder 640. Sync detector 725 indicates this detection via latch clock 726. At this time the data loaded within output latch 740 is valid.  
15 Therefore, output latch 740 generates keyboard data 741, mouse data 742 and speech data 743 corresponding to the data input to transmitter 600. This data is employed in graphics controller 120 and central processing unit 110. These signals from user terminal 130 are employed then to control the operation of the  
20 data processing apparatus.

## CLAIMS:

1. A video display device communications interface comprising:
  - a) a communications link for transmitting communications signals;
  - b) a video display generating device including:
    - 5 1) a video data encoder for generating a digital video signal having a plurality of video scan lines;
    - 2) a control data encoder for generating a digital control signal having self-clocking control data which has a lower data rate than said digital video signal;
    - 10 3) a multiplexing means connected to said video data encoder and said control data encoder for time division multiplexing said digital video signal and said digital control signal whereby said digital control signal is generated during the retrace intervals of video scan lines of said digital video signal thereby forming a multiplexed signal;
    - 15 4) a transmitting means connected to said communications link and said multiplexing means for generating communications signals on said communications link corresponding to said multiplexed signal;
  - c) a video display device including:
    - 20 1) a receiving means connected to said communications link for receiving said communications signals;
    - 2) a demultiplexing means connected to said receiving means for demultiplexing said communications signals into said digital video signal and said digital control signal having a self-clocking detection means for detecting said self-clocking of said digital control data thereby enabling detection of said control data, and a timed gating means connected to said self-clocking detecting means for enabling the operation of said self-clocking detecting means only during a time interval during which the retrace interval is expected;
    - 25 3) a video display means connected to said demultiplexing means for generating a visually perceivable display corresponding to said digital video signal; and

4) a utilization device connected to said demultiplexing means for receiving and using said digital control data.

2. A video display device communications interface as claimed in  
5 Claim 1, wherein:

said control data encoder further includes means for generating a predetermined sync bit pattern indicating the end of a video scan line of said digital video signal; and

said utilization device includes a sync bit pattern detection  
10 means for detecting the reception of said predetermined sync bit pattern and a horizontal reset means for beginning display of a new video line upon detection of said sync bit pattern.

3. A video display device communications interface as claimed in Claim 1, wherein:

15 said control data encoder further includes means for generating a predetermined vertical sync bit pattern indicating the end of a video frame of said digital video signal; and

said utilization device includes a vertical sync bit pattern detection means for detecting the reception of said predetermined  
20 vertical sync bit pattern and a vertical reset means for beginning display of a new video frame upon detection of said vertical sync bit pattern.

4. A video display device communications interface as claimed in Claim 1, wherein:

25 said digital control data comprises sound generation data; and

said utilization device comprises a sound generation means for generating sound corresponding to said sound generation data.

5. A video display device communications interface as claimed in  
30 Claim 1, wherein:

said digital control data comprises synthetic speech generation data; and

said utilization device comprises a synthetic speech generating means for generating synthetic speech corresponding to said synthetic speech generation data.

6. A video display device communications interface as claimed in  
5 Claim 1, wherein:

said communications link includes a fiber optic cable;

said transmitting means includes an optic fiber transmitter means connected to said fiber optic cable for generating digital light signals corresponding to multiplexed signal;

10 said receiving means includes an optic fiber receiver connected to said fiber optic cable for generating a demodulated signal corresponding to said digital light signals transmitted by said fiber optic cable.

7. A video display device communications interface as claimed in  
15 Claim 1, wherein:

said communications link includes a fiber optic cable having a first optic fiber and a second optic fiber;

said transmitting means includes a first optic fiber transmitter means connected to said first optic fiber for  
20 generating digital light signals corresponding to said multiplexed signal;

said video display generating means further includes:

a first optic fiber receiver connected to said second optic fiber for generating an output signal corresponding to  
25 light transmitted by said second optic fiber; and

a output means connected to said first optic fiber receiver for utilizing said output signal;

said receiving means includes a second optic fiber receiver connected to said first optic fiber for generating a demodulated  
30 signal corresponding to said digital light signals transmitted by said optic fiber; and

said video display device further includes:

an input means for receiving operator inputs and

generating input signals corresponding to said operator inputs;  
and

a second fiber optic transmitter connected to said input  
means and said second optic fiber for generating digital light  
5 signals on said second optic fiber corresponding to said input  
signals.

8. An input/output unit as claimed in Claim 7, wherein:  
said input means comprises a manually actuatable keyboard.
9. An input/output unit as claimed in Claim 7, wherein:  
10 said input means comprises a manually actuatable pointing  
device.
10. An input/output unit as claimed in Claim 7, wherein:  
said input means comprises a vocally actuatable speech  
encoding device.

## **Beschreibung**

### **Titel:**

Digitale elektronische Umschalteinheit für Bildschirm, Tastatur und digitale Eingabeeinheiten (z.B. Mouse), so daß mit einem Bildschirm, einer Tastatur und/oder einer weiteren digitalen Eingabeeinheit bis zu 512 Computer verschiedener Bauart gesteuert und bedient werden können.

### **Stand der Technik:**

Umschalter üblicher Bauart bestehen aus mechanischen oder einfachen elektronischen Schaltelementen. Alle Anschlüsse bis auf den einen, an dem gerade der Monitor, die Tastatur und/oder eine weitere digitale Eingabeeinheit angeschaltet sind, verhalten sich so, als wäre keine Einheit angeschlossen. Das führt dazu, daß es beim Aufruf vieler EDV-Programme, die die Verfügbarkeit von Mouse und/oder Tastatur am lokalen Computer erfordern, zum Systemabsturz kommt. Außerdem kommt es beim Start der Computer (Boot) wegen der fehlenden Eingabeeinheiten zu Systemfehlermeldungen und eine korrekte Initialisierung der Eingabeeinheiten findet nicht statt. Das bedeutet, daß nach dem Stand der Technik trotz des Umschalters sämtliche Computer mit den jeweiligen Eingabeeinheiten ausgestattet werden müssen, ohne daß diese, abgesehen vom Verhindern der Fehler und Systemabstürze, irgendeinen Nutzen haben.

Ein weiteres Problem der nach dem Stand der Technik vorhandenen Umschalter ist, daß alle angeschlossenen Computer über den gleichen Bildschirmstandard verfügen müssen, da die Umschalter nicht in der Lage sind, verschiedene Videosignale umzusetzen.

### **Problem:**

Zum einen werden heute in vielen Unternehmen und Institutionen nebeneinander Computersysteme unterschiedlicher Bauart mit unterschiedlichen Betriebssystemen (Software) unabhängig oder über ein oder mehrere Netzwerke eingesetzt. Vor allem bei heterogenen und großen Computernetzwerken stehen in den EDV-Zentralen auf engem Raum oft viele Computer. Jeder dieser Computer verfügt über eine Konsole bestehend aus Bildschirm, Tastatur und/oder einer weiteren digitalen Eingabeeinheit. An diesen Computern wird aber in der Regel nicht gearbeitet, so daß die Bildschirme, Tastaturen und sonstigen Eingabeeinheiten die meiste Zeit nutzlos herumstehen, also Platz, Energie und Kapital verschwenden. Bei den herkömmlichen Umschaltern bleiben die Eingabeeinheiten und Bildschirme unver-

zichtbar, da erstens fehlende Eingabeeinheiten zu Systemfehlern und Systemabstürzen führen und zweitens die Umsetzung verschiedener Grafikstandards auf ein zentrales Gerät nicht möglich ist.

Zum anderen muß in Computer-Schulungsräumen das Lehrpersonal die Möglichkeit haben, die Bildschirmplätze der Schüler einzusehen und ggf. Hilfestellung zu leisten, ohne ständig von einem Platz zum anderen zu laufen. Diesbezügliche auf dem Markt vorhandene Softwarelösungen sind oftmals unverträglich mit der Anwendungssoftware und belasten außerdem den Arbeitsspeicher.

Schließlich ist es in sehr großen Netzwerken (Wide Area Networks) aufgrund der räumlichen Entfernung der einzelnen Computer voneinander nicht möglich, sämtliche Computer an eine zentrale Konsole anzubinden.

#### **Vorteil durch Schutzanspruch 1**

Die im Schutzanspruch 1 angegebene Erfindung löst das Problem der Eingabeeinheiten und bietet darüberhinaus eine softwareneutrale Lösung, die weder den Arbeitsspeicher belastet noch Unverträglichkeiten mit der Anwendersoftware aufweist.

#### **Vorteil durch Schutzanspruch 2**

Mit den im Schutzanspruch 2 aufgeführten Merkmalen werden die lokalen Monitore entbehrlich.

#### **Vorteil durch Schutzanspruch 3**

Mit den im Schutzanspruch 3 beschriebenen Merkmalen ist es möglich, eine Vielzahl von Umschalteinheiten, an die jeweils eine Vielzahl von lokalen Computern angebunden ist, mittels einer Fernbedienungssoftware von einem übergeordneten Computer aus zu steuern und zu überwachen. Der übergeordnete Kontrollcomputer bewirkt dann durch softwaremäßige Einwirkung auf die zentralen Umschalteinheiten die hardwaremäßige Weitergabe der Signale an die lokalen Computer, während die Bildschirmsignale von den lokalen Computern hardwaremäßig an die zentrale Umschalteinheit weitergeleitet und von dieser softwaremäßig an den übergeordneten Kontrollcomputer übergeben werden.

#### **Lösung:**

An jedem Ausgang zu den Computern hin wird für die Tastaturen und anderen digitalen Eingabeeinheiten eine vollständige Emulation der betreffenden Einheit durchgeführt. Durch ein Multiplexverfahren werden unterschiedliche Bildschirmgrafikstandards über einen Multifrequenz-Monitor dargestellt.

Die Emulation der digitalen Eingabeeinheiten durch die im Schutzzumfang 1 angeführten Merkmale geschieht dadurch, daß jeder lokale Computer als Ersatz für die Tastatur und/oder eine andere digitale Eingabeeinheit eine digitale Schaltung erhält, die eine echte Tastatur oder andere Eingabeeinheit (z.B. Mouse) vollständig nachbildet. Die Darstellung verschiedener Grafikstandards auf dem im Schutzanspruch 2 beschriebenen Weg wird dadurch erreicht, daß die Bildschirmsignale der angeschlossenen lokalen Computer unabhängig vom jeweiligen Grafikstandard durch ein Multiplexverfahren zusammengeführt und zur Ausgabe auf einen zentrale Multifrequenzmonitor umgesetzt werden.

Die zentrale Überwachung und Steuerung sehr großer Computernetze durch die im Schutzzumfang 3 aufgeführten Merkmale geschieht dadurch, daß in der Umschalteneinheit anstelle von Bildschirm und Tastatur ein an eine spezielle serielle Schnittstelle RS 232 angeschlossener Computer die Ein- und Ausgabesignale erzeugt und aufnimmt.

#### **Erreichte Vorteile:**

Die Simulation einer Mouse ist nach dem Stand der Technik über eine Hardwarekonstruktion bisher überhaupt nicht möglich gewesen.

Außerdem wird erreicht, daß beim Starten (Boot) der lokalen Computer keine Systemfehler gemeldet werden und die Initialisierung der digitalen Eingabeeinheiten korrekt erfolgt, ohne daß diese Einheiten physikalisch vorhanden sein müssen. Außerdem können auch ohne diese Eingabeeinheiten Programme ausgeführt werden, die deren Verfügbarkeit voraussetzen und bei Fehlen der Einheiten Systemabstürze oder andere Funktionsstörungen verursachen. Schließlich benötigt man auch nur noch einen Monitor zur Steuerung und Überwachung sämtlicher angeschlossener Einheiten.

Damit werden Gerätekosten, Platz und Energie gespart und die Übersichtlichkeit bei der Systemadministration erhöht.

Der Vorteil der im Schutzanspruch 3 bezeichneten Erfindung liegt neben den vorbezeichneten Vorteilen darin, daß die Kontrolle selbst großer sich über große Entfernungen erstreckender Netzwerke von einem Platz aus möglich ist.

### **Beschreibung eines Ausführungsbeispiels:**

Die hier als Beispiel beschriebene Ausführung ermöglicht als 4-Kanal-Gerät die Kontrolle von 4 lokalen Computern. Die Zahl der Kanäle kann bis auf 512 erhöht werden.

Die Ausführung erfolgt in 19" Industriegehäuse-Bauweise oder als Einzelgerät zum Beistellen.

An der Vorderseite befinden sich die Tasten und Leuchtanzeigen für die manuelle und automatische Kanalumschaltung. (Bild 1- Frontansicht)

Die Zeitbasis für den automatischen Umschaltzyklus ist variabel einstellbar. Nicht beschaltete Kanäle können durch eine Überspringfunktion aus dem Zyklus herausgenommen werden.

An der Rückseite befinden sich je ein Stecker für Monitor, Tastatur und eine weitere digitale Eingabeeinheit und die Anschlüsse für die einzelnen Kanäle sowie eine serielle Schnittstelle RS 232 zum optionalen Anschluß an einen den Monitor und die Eingabeeinheiten ersetzenden Computer. (Bild 1- Rückansicht)

An jedem Kanal wird an einem Stecker ein Spezialkabel angeschlossen, das auf der Seite des jeweiligen lokalen Computers in eine dreiteilige Anordnung ausläuft, deren Enden jeweils mit dem Monitorausgang, dem Tastatureingang und dem Eingang einer weiteren digitalen Eingabeeinheit des lokalen Computers verbunden werden können.

Bei dem Spezialkabel handelt es sich um ein Bündel von Einzel- und Koaxialkabeln zur störungsfreien Übertragung der teilweise hochfrequenten Signale. Es besteht im einzelnen aus 6 x Koaxialkabel mit 75 Ohm Impedanz zur Übertragung der Videosignale, 4 x 0,25 mm<sup>2</sup> geschirmt zur Übertragung der Tastatursignale, 6 x 0,14 mm<sup>2</sup> ungeschirmt für weitere digitale Eingabeeinheiten und die für die Koppelung mehrerer Umschalteinheiten notwendigen Steuerfunktionen.

Die Funktionsweise ist aus den Abbildungen "Document Number 1 - 10" handnumeriert von I. - X. ersichtlich. Weiterführende Erläuterungen werden durch Großbuchstaben auf den Dokumenten zugeordnet.

**Schutzansprüche und Beschreibung**  
**nach GbmAnmV**

**Zentrale elektronische Steuereinheit für mehrere Computer**

**Schutzansprüche**

**Oberbegriff:**

1. Umschalteinheit, die die Leitungen zwischen Monitor und Tastatur auf der einen Seite und mehreren Computern auf der anderen Seite mechanisch oder elektronisch so umschaltet, daß mit einem Monitor und einer Tastatur und/oder einer weiteren digitalen Eingabeeinheit eine Vielzahl von angeschlossenen Computern dergestalt zyklisch oder wahlfrei bedient werden können, daß jeweils die Leitungen zu einem der Computer beschaltet sind
  - dadurch gekennzeichnet, daß an jedem Ausgang zu den Computern hin für die Tastaturen und anderen digitalen Eingabeeinheiten eine vollständige Emulation der jeweiligen Einheiten erfolgt, indem als Ersatz für die jeweilige lokale Tastatur und/oder andere lokale digitale Eingabeeinheiten diese Eingabeeinheiten durch eine digitale Schaltung am Tastatureingang und/oder der Schnittstelle für eine andere digitale Eingabeeinheit vollständig simuliert werden;
2. Umschalteinheit nach 1
  - dadurch gekennzeichnet, daß unterschiedliche Bildschirm-Grafikstandards auf seiten der Computer über einen Multifrequenzmonitor dargestellt werden können.
3. Umschalteinheit nach 2
  - dadurch gekennzeichnet, daß Bildschirm und Tastatur der zentralen Umschalteinheit über eine serielle Schnittstelle RS 232 durch einen Computer ersetzt werden.
